Five letter geospatial keywords Radar [,... ] Five letter geographic keywords Name of GIS Use of the two different sets of spatial keywords makes the use of this geospatial database of the North American State Geographic Coordinate System (GCS) Geographic Reference System (GRS) grid coordinate system reference system difficult. The GCS/GRS coordinate system grid is a rectangular coordinate system defined by a set of three dimensions, most notably two longitude and latitude coordinates and a depth distance, the depth distance being defined by the difference between longitude at high latitude and longitude at low latitude. The three dimensions of the grid are defined by the GRS as respectively X, Y, and Z values and are set as their respective units of degrees, meters, and meters. The common units of measurement for Z (distance in latitude) are degree-minutes and for X (longitude) degree-seconds. The GRS is referenced as the North American Datum of 1983 (NAD83). This means that the grid is divided into a rectangular area that has a cell width of three meters (six feet) and a cell length of two meters (six feet) in the direction of X and Y and twenty-four meters (seventy-two feet) in the Z direction. The grid is also divided into approximately fifteen degrees in the horizontal directions. In the common mapping software the reference to the GCS/GRS grid system is the "Geographic Coodinate System", and the unit of measurement is degrees of latitude (usually referred to as "latitide"), degrees of longitude (usually referred to as "longitide"), and meters (or feet or yards or whatever, but rarely meters in the United States). The GCS/GRS coordinate system has a primary reference to be the WGS 84 geodetic reference system (i.e. it is referenced to the WGS 84 ellipsoid) but the reference points to the origin of the coordinate system and the origin
