execJ is a fast and powerful Java Tool to create Windows executable files from Java Applications. It allows you to easily and quickly create Windows applications from any Java Application. It's easy to use and you only need to drag-drop-and-drop your Java Classes on a application. With execJ you can: * Create and distribute a single executable Java Application file. * Integrate with Windows Services. * Include Java Help documentation and embedded help files as an optional component of the application. * Compress embedded files, greatly reducing the size of the built executable, usually by 20% to 50%. * Create build tools to create multiple versions of an application. * Create Windows Services with Java. Experience Java Applications Today with Java Enterprise Edition 6 and Java Web 6 Tutorial Java is a robust platform for developing and deploying enterprise applications. Java apps are compact, secure, and quick to compile. In this tutorial, you will use the Java development environment and IDE. You will create a Java EE application with a web and EJB client. The app will include: * A Java servlet with an embedded JSF page that

exposes an EJB. * An EJB that retrieves a database row and displays the data. The Java EE API provides a consistent set of Java technology building blocks for deploying and running applications in the Java environment. It is designed to provide a consistent and manageable set of services that encapsulate and simplify networking, transactional, and other technical complexity so that Java developers can focus on their software. The embedded resource manager in execJ removes your need to package any proprietary files with your app. Just embed them in the project as files (e.g. jpg, tiff, or doc) or the special embedded resource mechanism and your app is ready to run on Windows. execJ You will also be able to seamlessly call functions from these embedded resources in your app. With embedded resources the file inclusion and filtering is entirely performed by the embeddee as it optimizes the inclusion and caching of these files and avoids duplicate files. Filtering is based on metadata and will match resources based on the path, extension, or content of the embedded file. But the embedded resource manager is not limited to the system resources. In addition to Windows resources, it can also embed Java classes, jar files, or any other application file. You can also embed compressed files. Calling classes from these resources is simple. Calling a function also works. The embedded resource manager is extensible. You can also extend it to support other types of resources besides Windows. ... Key Features of execJ: Embed any file in your application without dealing with file

Easily create and embed executable applications that work on Windows and other platforms. The embedded library classes and resources cannot be analyzed by a decompiler. Integrated with the Java Native Interface (JNI). Works with Java classes, resources, and binary data (classes, resources, images, executables, manifest files, etc.) Easy to use libraries that already work with Java. Parallel to Microsoft Visual J++ Direct support for Java (1.4.2 or later) The Java 2 Platform, Standard Edition (J2SE). The free version of the Active State Platform Framework. Runs under Microsoft Windows 2000 and later, Java 1.1.0 or later ExecJ File Format • Applications must support the `.exe` extension • The `.exe` extension can be anything you want • The `.exe` extension only indicates the type of file • The `.exe` extension is dropped at the time the execJ distribution is run. In many cases, it is best to simply name your executable file with your company name followed by the name of the company file such as My.COM or MyCompany.EXE, as this name is hard coded into execJ. The name of the file is used for the following purposes: • The name of the Windows executable file. •

The name of the Windows display name (for Java Windows services). • The name of the Java application package (for Java applications). The packaged files must have the following file extensions: • (JAR) Java archive • (Z) ZIP archive • (B) Raw binary (**no file extension) The following file types will also be properly compressed: • (T) Tar archive (**no file extension) • (G) TAR archive (**no file extension) • (L) LZ archive (**no file extension) • (C) CAB archive (**no file extension) • (S) ACE archive (**no file extension) User-friendly and easy to use, you'll have no trouble creating and packaging your Windows executable using only a few mouse clicks. You can distribute your application with a text-only description, an HTML or Word description, or you can embed some instructions in the binary (if it's a JAR application). You can even use other types

What's New In?

execJ is a Java-based project for the creation of Executable JARs. The JAR can be the basis for a Windows Service, a stand-alone EXE or run on top of a Java application. Windows Services can be run and managed in Windows. Since they are a service, they get scheduled to

automatically run when the computer starts. I will briefly demonstrate how to use execJ, for further information please see It is often necessary to create executable applications for use on a wide range of platforms and operating systems. These include Java, C/C++, C#, Visual Basic, Delphi, and others. In the past, these applications were created, deployed and installed via individually generated installers. An alternative is to use tools such as ActiveState MuleSoft's JRebel The JRebel approach makes it easy to deploy your application on any platform - there are no platform-specific installers to create, and the application does not have to be run to execute it. Starting from release 7 of ActiveState's JRebel, it is possible to create Java applications that are executable on any platform - not just the PC. This executable includes Java classes and resources as well as a manifest for Windows executables. An important aspect of this executable is the fact that it comes with no other applications, or any other components. Therefore it cannot be a virus, and this is a big benefit for corporate environments - no matter what anti-virus software or firewalls are in place, there is no risk of a virus being installed. For more information please see Running Windows services in Java using
