Q: Filtering an observable by another observable in angular I'm learning Rx and I'm getting the hang of things, but I'm still confused. I have a table of articles, which can be filtered by a

category (which is loaded asynchronously, and is given as input). I need to load only items in a category (in the example it's Books): The articles model contains a property of type `Object[]` and the categories model contains an `Array` of objects, which I want to filter the articles by. The observable that fetches data for the articles looks like this:

```
const articles$ =
this.afs.collection('articles',
).snapshotChanges().pipe( map(
changes => { let data =
changes.map(c =>
({ ...c.payload.doc.data() }))) return
{ article: data.filter(e =>
```

`this.articles.find(a => a.category === e.category)), total:
this.articles.length } }));` In my
template I use the `ngx-datatable` to
load the articles:

Google Play Music Desktop Player Crack + Download

Cracked Google Play Music
Desktop Player With Keygen is a

Desktop notifications for changes in your Google Play Music library. ?
Built-in audio equalizer for customizing the sound

quality. ? Stream audio and music from Google Play Music and other music services directly to Google's proprietary Google Music servers.

Q: python azure function that returns list of dictionaries I am very new to azure functions. I am currently using python azure functions for the first time and I need to return the results of a request to the external API that I am using. My request is returning a list of dictionaries that I need to iterate over to create a number of entities that are then stored in the database. My Azure function is defined in the way shown below.

```
def main(event, context): # do some
stuff responses = fetchResults() #
do some stuff return responses
function_name = container.get_jso
n("default",name='myFunction')
```

The 'fetchResults' method is defined as follows:

```
def
fetchResults(): #do some stuff
response= fetchProductsFromProd
uctID(product_id) #do some stuff
return response
```

The issue is that the function returns only one dictionary and the function is executed with one invocation of the function and the method is called only once. Is there a way to change how it is invoked so that the result of the

function is in the form of a list of dictionaries? Note 6a5afdab4c

Key features:
