In particular, the development of surface-reactive fire-retardant additives has proven to be an efficient approach. Among the many methods for designing fire-retardant polymers, surface-reactive additives are very promising because they do not alter the basic properties of polymeric materials and because they provide the possibility to control the surface characteristics of the final polymer. Such surface characteristics, or properties, include wettability, surface energies, charge distribution and morphologies. The contact of additives, with the polymer surface, and other additives, can lead to both physical and chemical changes. The latter, if they occur, can either prevent, slow, or enhance fire, depending on the chemical and physical properties of the polymer and of the additive. The synthesis of grafting additives from polymers is often done by direct copolymerization of the polymer itself and an additive, such as styrene. The polymer is dissolved in a good solvent and the additive is added. The mixture is then dispersed in a poor solvent, which leads to the precipitation of the grafted polymer, which can be then collected by filtration, evaporation, or other methods. In some cases, the grafted a1d647c40b
