The present invention relates to a method for producing components of an interconnect system, and more particularly to an improved method for producing interconnect components for use in an electronic system. As is known, interconnect systems are used in electronic systems to provide the desired electrical connection between electronic components in the system. In some electronic systems, it is desirable to provide a number of these interconnections in a small area. In order to meet this desire, the interconnect system typically includes a number of interconnect components which can be mechanically attached to provide the desired connections. In order to produce such interconnect components, a number of different processes are typically used. For example, U.S. Pat. No. 4,656,521, hereby incorporated by reference, shows an example of one such method. In this patent, a plurality of circular holes are formed in a piece of electronic material such as beryllium copper. The holes are then filled with solder which is then allowed to harden. Next, a sliver of copper or other conductive material is mechanically inserted into each of the holes. At this time, the sliver of copper or other conductive material is allowed to flow into the hole. This process can then be repeated for other holes to form the desired interconnections. Although, such a method of producing interconnect components can be used, there are problems with it. For example, the process is relatively slow and involves the use of solder. In addition, in the above-described process, there is a risk that the sliver of copper or other conductive material might be inserted into the wrong hole or that the sliver of copper or other conduct
