Subscribe to MacStories on YouTube for more videos. You might think Photoshop is for professionals only but if you've ever thought about joining the ranks of graphic designers, web designers or even photographers, this article is for you. There are many beginner Photoshop techniques and concepts to master that are just as valuable as the more advanced ones. In

---

this article, you'll learn the basic Photoshop concepts and techniques that you need to know to become a Photoshop wizard. Raster editing in Photoshop Before we get into the meat of this article, let's talk about the basics of what a raster is. A raster is the 3D model of an image. In the real world, we might recognize it as a photo or a painting. In computer graphics, we call it a raster. A raster is a standard sheet of paper with a definite size and dimensions. A photograph or drawing of a photo is a raster. In Photoshop, you work with rasters by creating layers (the digital equivalent of a photo and drawing at the same time) and moving and editing those layers. A Raster Photoshop defines a raster as a template of an image. It could be a photograph, a painting, a manga drawing, a graphite drawing, etc. Each layer of a photograph or drawing is a raster. Each layer, like each block of a raster template, is a separate Photoshop document with its own “paper” size, layer type, and layer settings. If you

---

want to learn more about how to create layers and how to create templates, you can read this article on Layer Style Basics. Layers The layers in Photoshop are like the blocks you can see in a raster. There are multiple layers, one for each block in the raster. A layer is a Photoshop document, just like a raster. Layers can have different layer types and layer settings as well. You can merge or delete any layer in Photoshop. This is the equivalent of making adjustments to the raster template. Lightroom Lightroom is Adobe's photo editing and management software. Like Photoshop, Lightroom lets you create and edit layers as you work with photos and give them different adjustments. What's the difference between Photoshop and Lightroom? Photoshop can open and save in RAW file formats. Lightroom is designed to edit photos in the RAW file format. It a681f4349e

**Q: Nearest Neighbourhood Calculator** The question I am trying to implement is to calculate the k-nearest-neighbour nearest[points] with nearest[points,k]. I have seen some questions on Stackexchange that mentions implementing the nearest-neighbour k-means algorithm, in which the k-nearest-neighbour neighborhood are the k-means centers. I have no idea how to approach it, but my biggest challenge is understanding the mathematics of the algorithm. I would greatly appreciate any help.

**A:** I am not entirely sure what you are asking, so take this as a first attempt. Lets assume you have a set of points in a two-dimensional space, where each point has an associated value. Now, assume that you want to find the 10 closest points to a given point. First, you decide on a value k, which represents the maximum number of points you

---

are interested in. We could do this by examining every point in the data. Then, you need to decide on which points to include in the "neighbourhood". We could simply include the  $k$  closest points to the given point. However, there are better ways to do this. For example, we could decide on a "radius" value, which would define the distance between points included in the neighbourhood. We could then define the neighbourhood as the points located within this radius. Finally, we must calculate how many times each point is included in the neighbourhood. There are a couple of different ways to calculate this. The simplest way is to count the number of times a point is included in the neighbourhood. We can define a points-in-neighbourhood: `points-in-neighbourhood[points, radius]` which counts how many points in `points` are within the given radius. EDIT: Based on your subsequent questions, the above should still be a good start. For more detail, I would suggest reading this

---

tutorial. I would also suggest reading the Nearest Neighbour Class. If the above is still unclear, please let me know. for creating VL\_GLOBAL() # if! defined (\_\_GLIBC\_\_) # define VL\_GLOBAL(type) type VL\_LOCAL() # else # define V

### What's New In?

Q: Why doesn't the background colour of my label change upon changing the value of a textbox?

Basically, I have a working GUI. If you start typing in a textbox, the background of the label changes to a red colour as appropriate. However, if the textbox is empty, it should change to a blue colour. However, it doesn't. GUI output The label should be blue if the textbox is empty but red if it isn't. Here is my code:

```
#include #include #include using namespace std; int main() { int x; bool txt = false; bool in = false; string newText; //textbox cout > x; cout > x; } if (in) { cout
```
