has become a first line clinical tool for the detection and quantification of atherosclerosis, using T2-weighted sequences. This is mainly due to the high contrast between plaque and vessel wall, and, in combination with the development of multi-contrast techniques, the accurate quantification of atherosclerotic plaque. In addition, the low time-consuming of an MRI exam, the possible non-invasiveness, and the ability to image atherosclerotic plaque from different angles make it an attractive tool to be used in the diagnostic and therapeutic pathway of the patient with atherosclerosis. However, quantitative accuracy and repeatability of the measurements are still issues which should be addressed. In the last decade, numerous studies have investigated the correlation between carotid atherosclerotic plaque, detected by different sequences, and clinical
