Improving the separation of bismuth from lead by bubble columns in a fused-core-shell column. Bismuth and lead in fly ash are separated from each other by bubble columns with two fused-core-shell columns of different outer diameters, 0.5 mm and 0.65 mm. The bubble columns are connected in series with two steel tubing columns to improve selectivity. The separation conditions are investigated as a function of both the column packing densities and the kinetic contact time. The bubble column with a smaller outer diameter is more effective for separating bismuth from lead than the other bubble column. At the same time, the separation of bismuth from lead in the smaller bubble column is less sensitive to the column packing densities than that in the large bubble column. This finding has important implications for the design of a bubble column, because it means that the required packing density can be decreased in order to improve separations. It is generally known to provide a golf cart with an internal power source to propel the cart. Generally, the internal power source is a combustion engine. It is also generally known to provide a golf cart with an external power source to recharge the internal combustion engine. Moreover, it is generally known to provide a golf cart that has some means of storing power generated by the internal combustion engine during periods of inactivity of
