Granite Rail Bridge The Granite Rail Bridge, also known as the Mt. Hope Bridge, is a historic railroad bridge connecting the town of Granite and the town of South Granville in the U.S. state of New Hampshire. The lone railroad trestle bridge within the town of Granite was built in 1901-1902 to link a rail line from the Maine–New Hampshire border and the U.S. town of Beverly with the Smithfield-Springfield rail line, which crossed the Ammonoosuc River to the south. The single-span wooden trestle was built by the Southern New England Railway, an interurban line that also crossed the river to reach New Boston, approximately south. The bridge was added to the National Register of Historic Places in 2002. Simultaneous measurement of intercellular
adhesion molecule 1 and vascular adhesion molecule 1
on peripheral blood mononuclear cells using novel
fluorescent multiplex beads in clinically stable multiple
sclerosis. Multiple sclerosis (MS) is a disease of the
central nervous system (CNS). Infiltrating
inflammatory cells, including lymphocytes and
macrophages, play an important role in the
pathogenesis of the disease and can be detected in the
peripheral blood of patients with MS. However, data
from blood are, to some extent, limited as some of the
pathologic signs of the disease are more likely to be
evident in the CNS than in the blood. We aimed to
measure simultaneously soluble intercellular adhesion
molecule 1 (sICAM-1) and vascular cell adhesion
molecule 1 (sVCAM-1) on peripheral blood
mononuclear cells (PBMCs) from MS patients, and

related these measurements to clinical disease activity. We developed a novel protocol for flow cytometric analysis of the phenotypic markers sICAM-1

Chemotherapy-related fatigue with dynamic changes in cytokine profiles in plasma. We evaluated cytokine levels in plasma during chemotherapy with or without granulocyte colony-stimulating factor (G-CSF) in patients undergoing adjuvant chemotherapy after curative resection for gastric cancer. Preoperative plasma cytokine levels were assessed in 36 patients before the start of chemotherapy. All patients received chemotherapy, and patients who were seropositive for human T-cell lymphoma virus type-I (HTLV-I) were given G-CSF at a dose of 5 mg for 2 days. After 8-11 weeks of chemotherapy, the levels of interleukin (IL)-1beta, IL-6, IL-8 and tumor necrosis factor-alpha (TNF-alpha) in plasma were measured again. The levels of IL-1beta, IL-8 and TNF-alpha were significantly higher in the patients who did not receive G-CSF. The majority of patients who received G-CSF

showed lower levels of IL-1beta, IL-8 and TNF-alpha in plasma. These results suggest that chemotherapy-induced fatigue related to cytokines is reduced in patients who receive G-CSF.1. Field of the Invention

The present invention relates to a method for fabricating a semiconductor device. 2. Description of the Related Art

With an increasing miniaturization of a semiconductor integrated circuit device, it is necessary to reduce an exposure amount of a wafer, for example. The exposure amount of a wafer, however, generally has a maximum resolution limit due to problems such as a finite depth of focus. In order to reduce the exposure amount, multi-step exposure technology has been proposed. The multi-step exposure technology is such that the exposure amount is changed stepwise during exposure of an entire area of a wafer. Thus, a smaller exposure amount can be set than a resolution limit even when the exposure amount is changed stepwise. A method for reducing the exposure amount in the multi-step exposure technology will be briefly described below. First, a mask is divided into multiple units of exposure areas, and the exposure area is divided into multiple partial areas. The multiple units

of exposure areas are repeated in multiple layers, with the exposure area being repeated in the multiple layers. At this time, a number of exposure areas divided into a single exposure area is normally 10 times or 20 times as large as the number of exposure areas of the entire
